Emotion recognition in the wild

- Challenges
  - Large data variations
    - head pose, illumination, partial occlusion, etc.
  - Lack of labeled data
    - Manual annotation is hard as spontaneous expression is ambiguous in the real world.

Video-based emotion recognition

- Acoustic information based
  - Time domain and frequency domain
    - e.g. pitch, intensity, pitch contour, Low Short-time Energy Ratio (LSTER), maximum bandwidth, …
- Vision information based
  - Spatial space and temporal space
    - e.g. Optical flow, 3D descriptor (LBP-TOP, HOG 3D), tracking based (AAM, CLM), probabilistic graph model (HMM, CRF), …

Our method

- Key issue
  - How to model the emotion video clip?
- Motivation
  - Alleviate the effect of mis-alignment of facial images
  - Encode the data variations among video frames
- Basic idea
  - Inspired by recent progress of image set-based face recognition [1]
  - Treat the video clip as an image set, i.e., a collection of frames
  - Linear subspace for video (image set) modeling

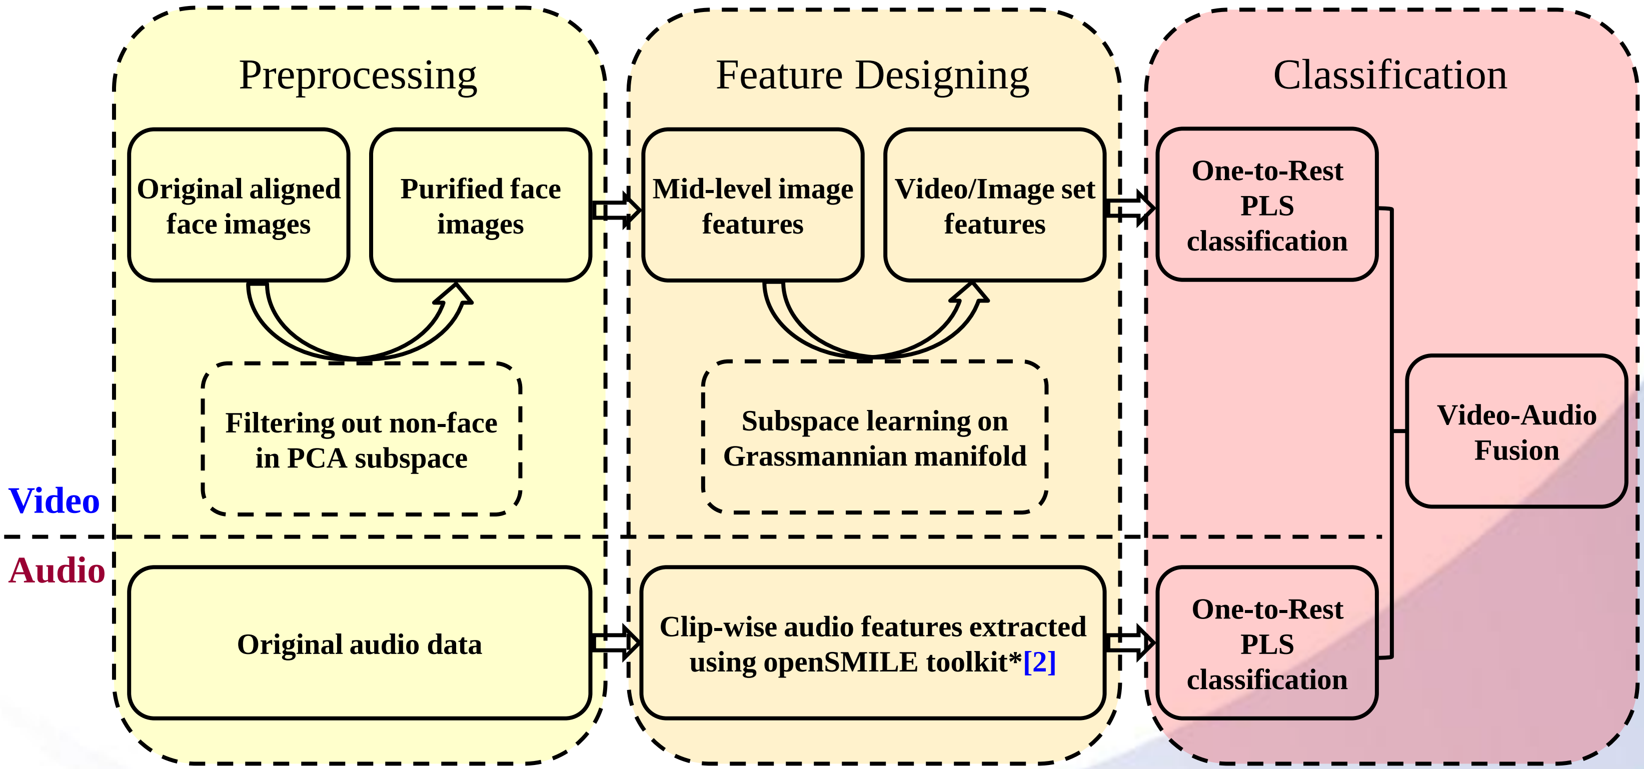
Our method

- An overview



[2] F. Eyben, M. Wollmer, and B. Schuller. Opensmile: the munich versatile and fast open-source audio feature extractor. ACM MM, 2010.

Our method

- Preprocessing
  - Original face alignment using MoPS [3] (*provided by organizer*)
  - Purification of face images
    - Original aligned face images set: $X = \{x_1, x_2, \dots, x_n\}, x_i \in R^D$.
    - PCA projection learned on X by preserving low energy: W.
    - Mean reconstruction error of each image:

$$MeanErr_t = \frac{1}{D} \left|\left|x_t - W^T W x_t\right|\right|^2$$

    - Non-face/Badly-aligned face images tend to have large $MeanErr_t$.

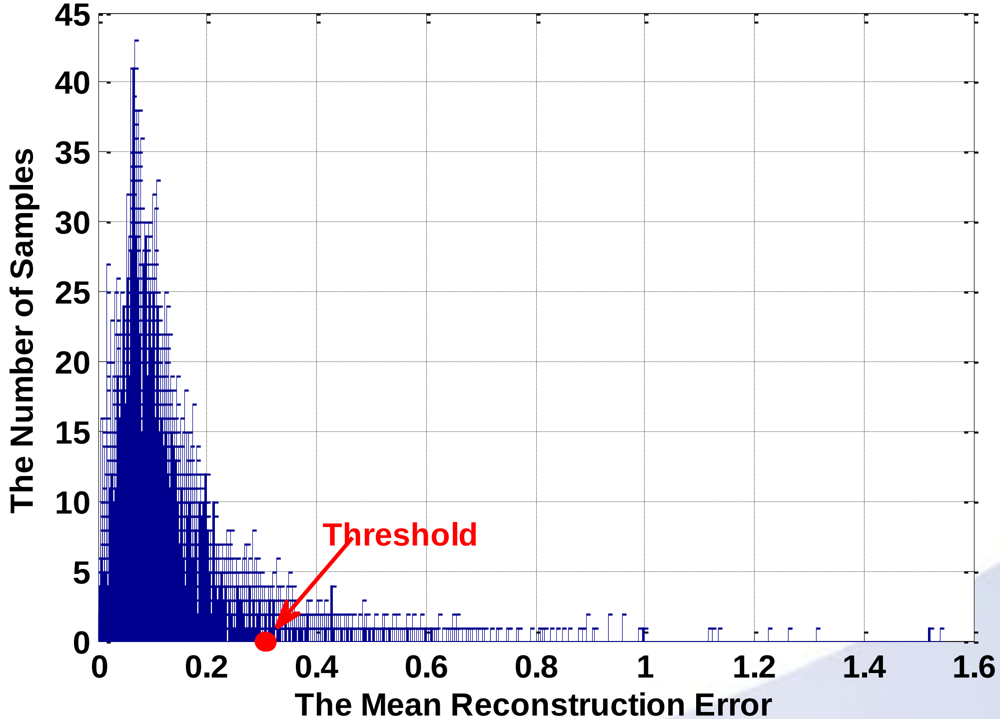
Our method

- Preprocessing
  – The distribution of $MeanErr_t$ on training set in EmotiW2013.



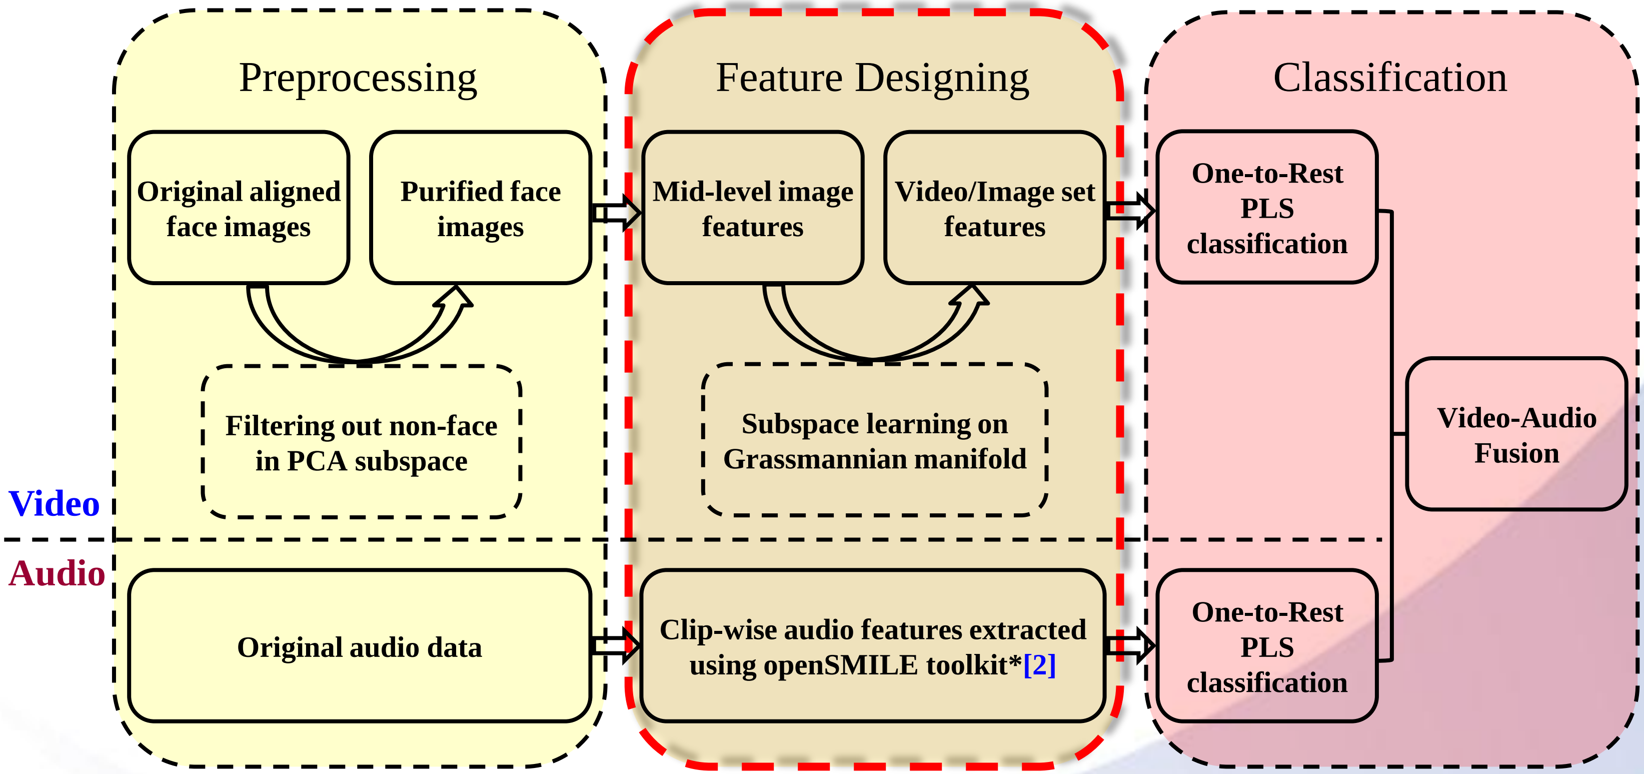
* Threshold is for filtering out non-face in PCA space.

Our method

- Preprocessing
  - An example of 100 samples with largest mean reconstruction error. Most are non-face images or mis-alignment results.

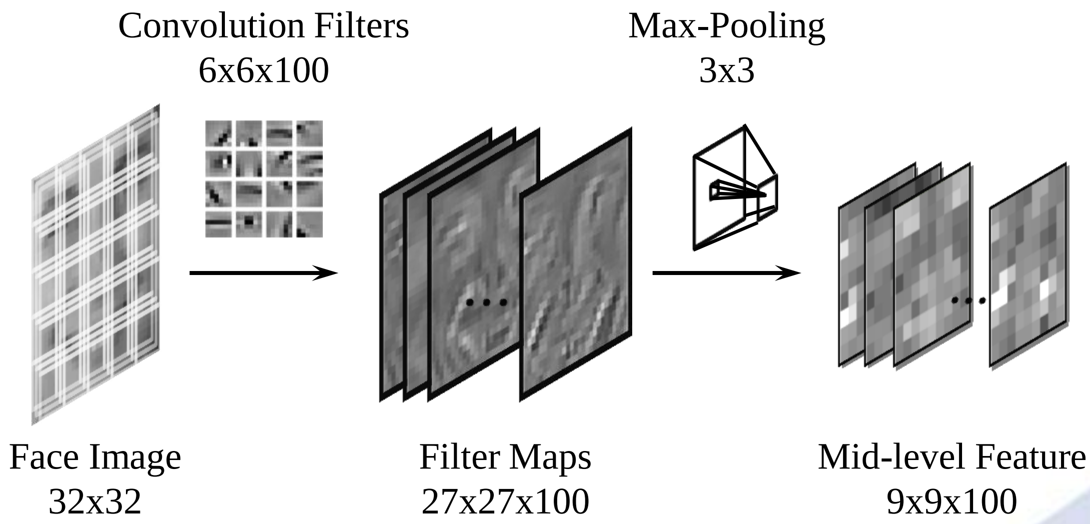
Our method

- An overview



Our method

- Feature designing
  - Image feature [4]



[4] M. Liu, S. Li, S. Shan, X. Chen. AU-aware Deep Networks for Facial Expression Recognition. FG, 2013.

Our method

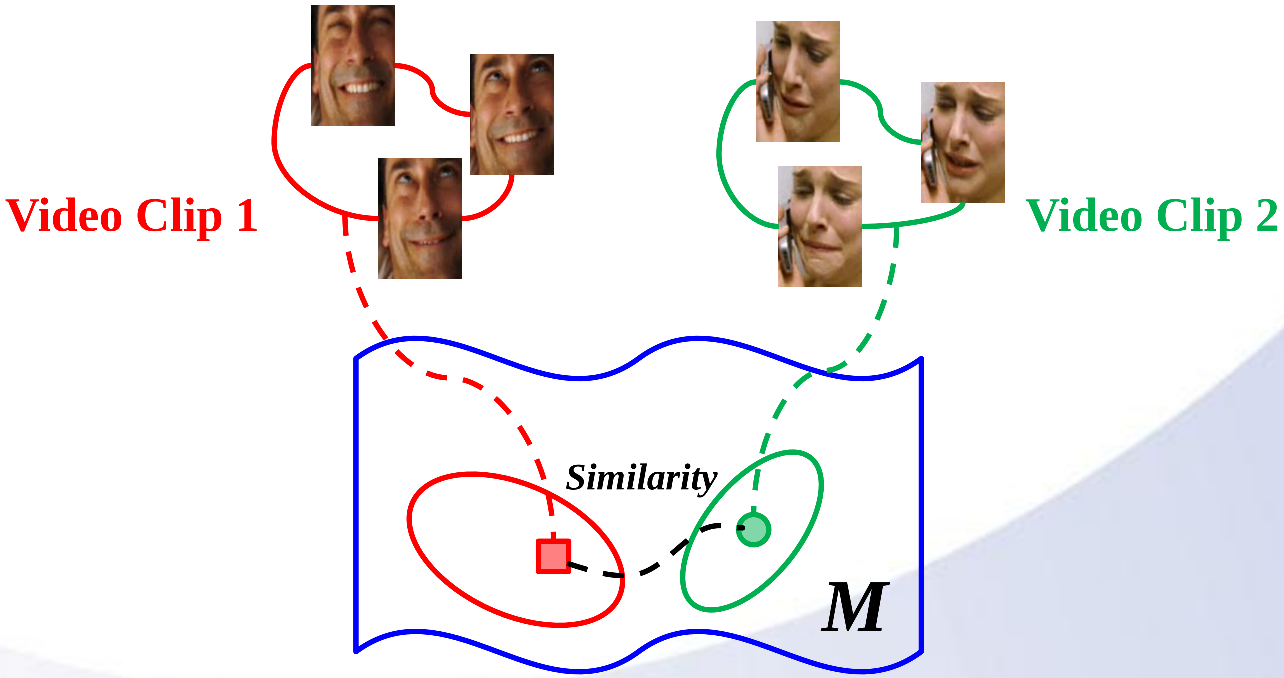
- Feature designing
  - Video feature
    - Each video clip is a set of images, denoted as $S_i \in R^{f \times n_i}$, where f is the dimension of image feature, and n_i is the number of frames.
    - The video S_i can be represented as a linear subspace P_i, s.t.

$$S_i S_i^T = P_i \Lambda_i P_i^T$$

    - Thus all the video clips can be modeled as a collection of subspaces, which are also the points on Grassmannian manifold.

Our method

- Feature designing
  - Video feature
    - An illustration of subspaces on Grassmannian manifold



Our method

- Feature designing
  - Video feature
    - The similarity between two points $\boldsymbol{P_i}$ and $\boldsymbol{P_j}$ on manifold M can be measured by a linear combination of Grassmannian kernels.
      - Projection kernel[5]: $k_{ij}^{[proj]} = ||P_i^T P_j||_F^2$.
      - Canonical correlation kernel[6]: $k_{ij}^{[CC]} = max_{a_p \in span(P_i)} max_{b_q \in span(P_j)} a_p^T b_q$.
      - Linear combination: $k_{ij}^{[com]} = k_{ij}^{[proj]} + \alpha k_{ij}^{[CC]}$.
    - The kernels of each point (i.e., each video) to all training points serve as its final feature representation for classification.

Our method

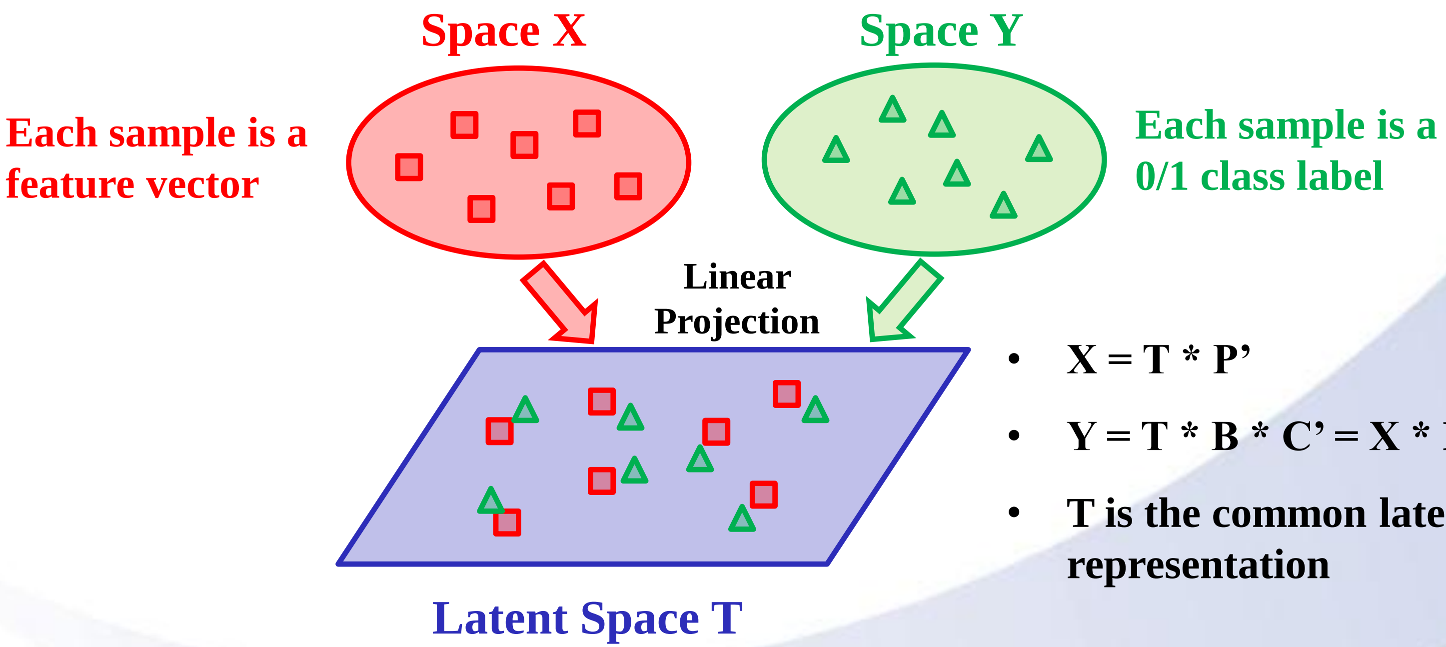
- Classification
  - Partial Least Squares (PLS) for classification [1]
    - Maximize the covariance between observations and class labels

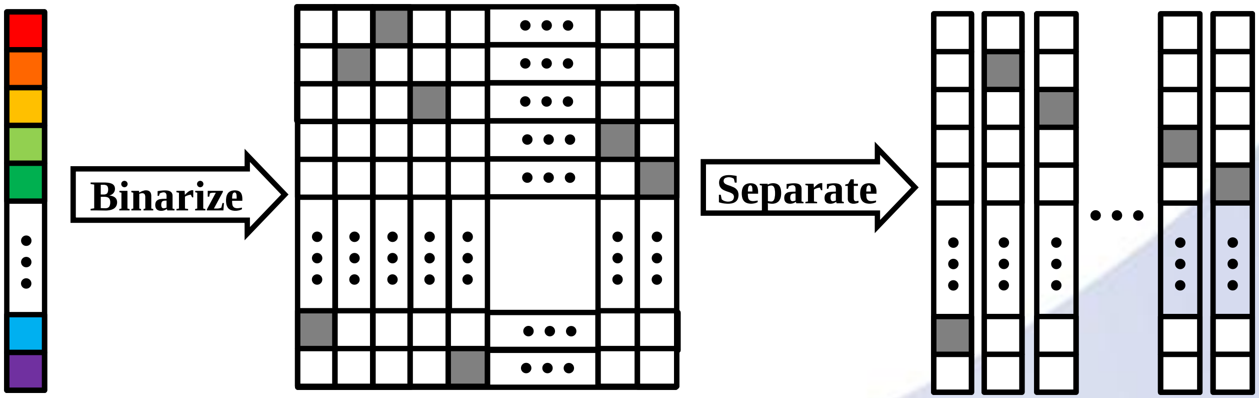


- X = T * P’
- Y = T * B * C’ = X * B_pls
- T is the common latent representation

[1] R. Wang, H. Guo, L. S. Davis, and Q. Dai. Covariance discriminative learning: A natural and efficient approach to image set classification. CVPR, 2012.

Our method

- Classification
  - One-to-Rest PLS
    - Suppose there are ***c*** categories and ***N*** training samples, we train ***c*** One-to-Rest PLS classifiers to predict each class simultaneously.
    - Effectively to handle the hard classes, e.g. "*Sad*" vs. "*Disgust*"



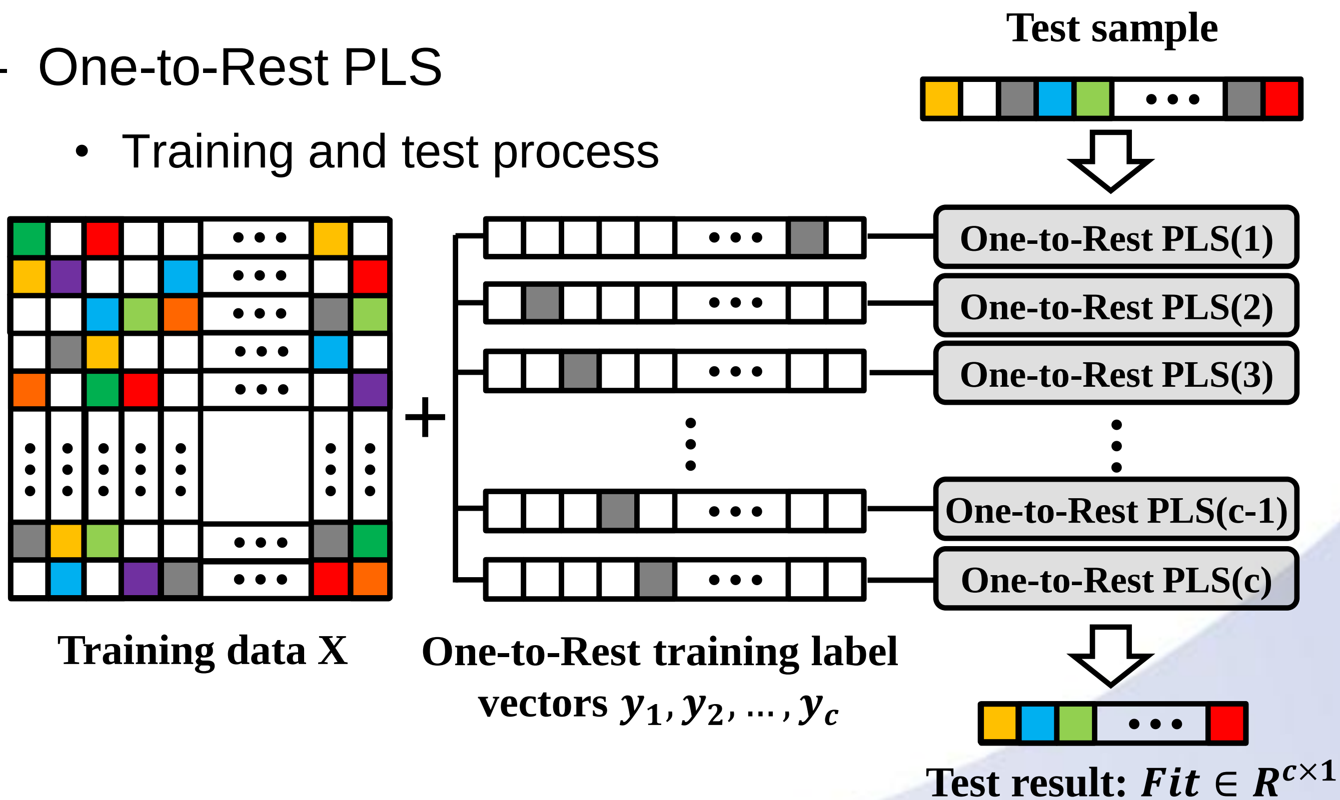
Original training label vector $\boldsymbol{Y} \in \boldsymbol{R}^{N\times 1}$

Binary training label matrix $\boldsymbol{Y} \in \boldsymbol{R}^{N\times c}$

One-to-Rest training label vectors, $\boldsymbol{y}_1, \boldsymbol{y}_2, \ldots, \boldsymbol{y}_c \in \boldsymbol{R}^{N\times 1}$

Our method

- Classification
  - One-to-Rest PLS
    - Training and test process



Our method

- Classification
  - Video-Audio fusion for final test output
    - For a given test video, using the *c* PLS classifiers for video and audio respectively, we obtain two prediction vectors $Fit^{video}, Fit^{audio} \in R^{c\times 1}$.
    - We conduct a linear fusion at decision level using weighted parameter λ

$$Fit^{fusion} = (1-\lambda)\ Fit^{video} + \lambda Fit^{audio}.$$

    - The category corresponding to the maximum value in $\boldsymbol{Fit^{fusion}}$ is determined to be the recognition result.

- Our Method
- Experiments
- Conclusion

Conclusion

- Key points of the current method
  - PCA-based data purifying to filter out mis-alignment faces
  - Linear subspace modeling of video data variations
  - Multiple video features fusion by Grassmannian kernels combination
  - Multi-modality fusion at decision level of video and audio
- Issues to further address
  - Exploration of video temporal dynamics information
  - More sophisticated video modeling
  - More effective fusion at feature level
  - …

Thank you.
